Patent claims

1. A device for family planning and/or contraception, whereby the device has
a means (1) for determining basal temperature,
a means (7) for input of the first day of the cycle,
a means (8) for input of the property of the saliva,
a device for processing the data (13) made available by the means (1, 7, 8),
a memory device (14) for storing at least some of the data made available and
a display device (4),
whereby the device for processing the data is designed such that a conclusion
regarding the woman's fertility on any given day is determined as a function of at least
some of the data made available by each means and this conclusion can be displayed
via the display device.
2. The device according to Claim 1, characterized in that the device for processing the
data is designed so that the data is weighted differently in determining the conclusion
regarding the woman's fertility.
3. The device according to Claim 2, characterized in that the weighting of the data can be
varied as a function of the stored data formerly made available.
4. The device according to one of the claims 2 to 3, characterized in that the conclusion
regarding the woman's fertility depends on the data made available by the means (1)
for determining the basal temperature to a greater extent than on the data made
available by the means (7) for input of the first day of the woman's cycle, and the data
made available by the means (7) for input of the first day of the woman's cycle in turn
has a greater influence on the conclusion regarding her fertility than does the data
made available by the means (8) for input of the properties of the saliva.
5. The device according to one of the Claims 2 to 4, characterized in that the weighting
made available by the means (1) for determining the basal temperature preferably
amounts to 50-90 %, especially preferably 60-80 %; the weighting of the data made
available by the means (7) for input of the first day of the woman's cycle preferably
amounts to 5-35 %, especially preferably 10-30 %, and weighting of the data made
available by the means (8) for input of the properties of the saliva preferably amounts
to 2-20 %, especially preferably 5-15 %.
6. The device according to one of the previous Claims, characterized in that the device is
equipped for processing data, such that the conclusion regarding a woman's fertility
differentiates between possible fertile and infertile days and that the possible fertile
and infertile days are displayed visually in different ways.
7. The device according to Claim 6, characterized in that the display device shows the
possible fertile days in red and the possible infertile days in green.
8. The device according to one of the Claims 6 to 7, characterized in that transition days
are also provided in the conclusion regarding the woman's fertility; these are days
when no distinction is made between possible fertile days and possible infertile days,
and the transition days are displayed differently visually than the possible fertile days
and infertile days.

-18-

9. The device according to Claim 8, characterized in that the display device displays the transition days in yellow.
10. The device according to one of the Claims 6 to 9, characterized by a means for recognizing an increase in temperature from the data made available by the means (1) for determining the basal temperature, whereby in determining the conclusion regarding the woman's fertility, a distinction is made between a first phase of the cycle at the beginning of the cycle and a second phase of the cycle after the rise in temperature is detected.
11. The device according to Claim 10, characterized in that up to a first point in time, for example, the end of the second cycle registered by the device, the number of possible fertile days is preslected in the conclusion regarding the woman's fertility in the second phase of the cycle.
12. The device according to Claim 11, characterized in that after the first point in time, the number of possible fertile days is determined as a function of an analysis of stored data in the conclusion regarding the woman's fertility in the second phase of the cycle.
13. The device according to Claim 12, characterized in that an indicator for the regularity of the duration of the cycle and/or the course of the cycle is derived from the stored data, and the number of possible infertile days is determined as a function of this indicator and/or the number of cycles registered by the device is determined in the conclusion regarding the woman's fertility in the second phase of the cycle.
14. The device according to one of the Claims 10 to 13, characterized in that the number of possible fertile days is determined and/or influenced as a function of the data made available by the means (8) for input of the properties of the saliva in the conclusion regarding fertility in the second phase of the cycle.
15. The device according to one of the Claims 10 to 14, characterized in that up to a second point in time, e.g., the end of the fifth cycle registered by the device, the number of possible infertile days is preslected in the conclusion regarding the woman's fertility in the first phase of the cycle.
16. The device according to Claim 15, characterized in that after the second point in time, the number of possible infertile days is determined as a function of an analysis of stored data in the conclusion regarding the woman's fertility in the first phase of the cycle.
17. The device according to Claim 16, characterized in that a quality factor is derived from the stored data, and after the second point in time, in the conclusion regarding the woman's fertility in the first phase of the cycle, the number of possible infertile days is determined as a function of the quality factor and/or the number of periods registered by the device is determined as a function of some data from the means (7) for input of the first day of the cycle.
18. The device according to one of the previous Claims, characterized by a time measuring device and an interactive device for instructing a user to input data after a predetermined period of time has elapsed.

-19-

19. The device according to Claim 18, characterized in that the interactive device is designed so that an input of the properties of the saliva is instructed preferably 5-10 times per cycle, especially preferably 6-8 times per cycle.
20. The device according to one of the previous claims, designed so that fluctuations in temperature that are not due to the cycle but instead are caused by other factors such as a cold or a migraine are recognized and then to discard this data when determining the possible fertile and/or infertile days.
21. The device according to one of the previous claims, designed so that a cycle and in particular the duration and/or the course of the cycle are recognized.
